Maul Foster and Alongi, Inc. (MFA) has prepared this report detailing our engineering due diligence for the potential remediation of the Deschutes County (County) Demolition Waste Landfill (site) to assist Oregon State University (OSU) in its evaluation of future campus expansion.

BACKGROUND

The site is an inactive construction and demolition waste landfill that was previously a pumice surface mine. The site was developed in three distinct landfill areas: Area 1, Area 2, and Area 3. The limits of waste in each area are delineated into three cells: Cell 1, Cell 2, and Cell 3. The landfill operated under an Oregon Department of Environmental Quality (DEQ) Solid Waste Permit from 1972 to 1996 to dispose of construction and demolition waste, industrial waste, woodwaste, brush, and tires. Cell 2 and Cell 3 were closed in 1997. Cell 1 (the eastern 23-acre portion of the site) closure certification from DEQ has not been received because a portion of the waste is undergoing pyrolysis. The pyrolysis is preventing the site, as a whole, from receiving official permitted closure.

MFA has discussed the landfill's history, closure, and regulatory requirements in association with redevelopment with the DEQ Solid Waste engineer, Joe Gingerich, P.E. Mr. Gingerich indicated that DEQ envisions all remediation and redevelopment work would be completed under the existing Solid Waste Disposal Site Closure Permit. Mr. Gingerich also noted that DEQ would require pyrolysis in Cell 1 to be addressed through excavation or other means. This remediation and redevelopment work could be incorporated into the DEQ's Prospective Purchaser Agreement process, if desired by OSU. DEQ stated that they see removal of the waste and extinguishing of the pyrolysis in Cell 1 as an environmental benefit.

INITIAL SITE ANALYSIS

For the initial site analysis, MFA reviewed all available landfill studies and reports and identified two main data gaps: 1) landfill cap material quality and its suitability for use as clean fill, and 2) whether landfill-related compounds, including methane- and non-methane-related volatile organic compounds (VOCs), are present in soil gas at the Site. MFA performed a site investigation and found that the cover soil can be used as clean fill, and that both methane and VOCs are present in subsurface soils.

Initial Remediation Scenarios

MFA initially evaluated developing over waste in its current location in an effort to minimize disturbance to existing conditions. The existing waste in Cells 2 and 3 could be left in place, however Cell 1 will require implementation of other remediation methods due to the presence of pyrolysis in the cell and the regulatory requirement to extinguish the pyrolysis in order to attain final closure.

Development over waste would require structural ground reinforcement such as piles or rock columns to stabilize structure and utility foundations against differential settlement and seismic

impacts. Development over existing waste would also require long-term monitoring and maintenance of the entire landfill. Leaving the waste in place poses some risks, such as differential settlement, methane gas exposure, and the potential of future pyrolysis. We don't see pyrolysis as an issue for Cells 2 and 3 or for Cell 1 waste that has been processed and relocated. Due to the arid climate, the absence of shallow groundwater, and the lack of contaminants in deep groundwater, leachate control does not appear warranted.

MFA also evaluated excavating and hauling all waste off-site to the local landfill. Accepting all waste from the site (over 2.4 M cubic yards (cy)) would greatly reduce the lifespan of the receiving landfill (Knott Landfill). This factor, along with hauling costs, landfill tipping fees, and the negative environment and community impacts of significant heavy truck-traffic (over **101,000 truck trips**) in local neighborhoods makes this option unacceptable.

MFA assessed the potential of screening and sorting waste at a material recovery facility (MRF), to separate the waste into recyclable materials, reusable materials, and rejected materials. However, the results of the Deschutes County pilot study indicated that the amount of recoverable material available is much less than originally estimated. Based on the results of the pilot study, this is not an effective option for site remediation.

Based on the findings listed above, our discussions with DEQ, feedback from the OSU team, review of background documents provided by OSU, and field investigations, MFA refined the following remediation options.

Waste Removal

Waste could be excavated in full from Cells 1 and 2. Excavated waste could be stockpiled for screening and reuse, or relocated to an expanded Cell 3. Prior to waste removal, the existing cover soil would be removed and stockpiled on-site for future reuse as backfill.

Cell 1 has additional considerations in the removal of waste, including pyrolysis, the near vertical face of the pumice mine on the east side of the cell, and the tires contained in the waste.

Cell 3 waste will most likely remain in place. Developing of Area 3 for passive use, such as sports fields, park, or parking lots, could occur on top of existing waste and relocated Cell 1 and Cell 2 waste without requiring major structural ground reinforcement.

Waste Screening

Excavated materials would require screening to separate fines (such as ash and gravel) from debris. Screenings could be stockpiled for use as backfill or reconsolidated in an expanded Cell 3.

MFA evaluated the potential of sorting waste into recyclable, reusable, and rejected materials. As part of this evaluation, results of a materials separation pilot study completed by Deschutes County in late August, 2016 were reviewed. The results of the pilot study indicate that the amount of waste and its suitability for recovery is low when standard screening/separation methods are employed. Specifically, the results suggest that the overwhelming majority of material in Cells 1 and 2 are high organic content fines (after separation using standard methods), making them unsuitable for structural fill without amendment.

MFA also obtained a sample of screened fines from the pilot study excavation and submitted it for agricultural testing. Results show the material contains inadequate nutrients for use as a compost feedstock. The material may be used as a soil amendment, but the low market value for this material is not expected to provide adequate net revenue.

Screened Fines Beneficial Reuse

MFA evaluated a potentially viable option of blending the screened fines with soil sourced on-site (i.e., cover soil and excavated native material) for reuse as backfill throughout the site. The small batch of screened fines obtained from the pilot study have a high organic content (22%), but could be blended with additional clean soil to produce a backfill material with an organic content suitable for development (4%). Based on this limited test, the screened material would require blending with soil at a ratio of 4.5 to 1. At this ratio, there is not enough soil on-site to be able to blend the entire volume of screened fines; however, a different screening method could be developed to reduce the breakdown of the larger wood debris and thereby reduce the screened fines organic content, resulting in a lower soil-to-fines blending requirement. This increases the amount of screened waste that can be used as blended backfill material. The excess screened fines could be used as cell cover soil and topsoil for landscape areas, or relocated to Cell 3. Large wood material separated during the screening process would be relocated to Cell 3 and consolidated into a single area. This wood material can then later be removed or repurposed as needed by OSU.

Relocation to Expanded Cell 3

Excavated waste could be consolidated on-site to Area 3. Cell 3 sits within a depression, and if the cover soil were removed, there would be roughly 450,000 cy of additional capacity to landfill waste. The proposed landfill cell could also be expanded south beyond the existing waste footprint of Cell 3, but still within the limits of Area 3. Native material could be excavated from this area to create an additional 581,410 cy of storage capacity for waste, and then be used as backfill elsewhere on-site. This would provide a total of 1,031,410 cy of capacity in Area 3, which is enough capacity to facilitate all the waste from Cell 1 and Cell 2—after repurposing a portion of the screened waste for backfill, cover soil, and top soil.

Maintaining a landfill cell on-site will require landfill gas (LFG) monitoring and long-term maintenance. Limited groundwater monitoring is also anticipated. It could also put some restrictions on future development over the waste footprint. Additional structural and ground improvements may be needed to support structures. Also, stormwater facilities should be constructed outside of the waste footprint or otherwise designed to avoid infiltration and leachate generation.

INTRODUCTION AND BACKGROUND

Maul Foster and Alongi, Inc. (MFA) has prepared this report to provide Oregon State University (OSU) Cascades the findings of the engineering due diligence for remediation and reuse of the former Deschutes County Demolition Waste Landfill (site). MFA has been working in collaboration with the OSU team, which includes OSU-Cascades leadership, engineering faculty, and the Long R:\1290.01 Oregon State University-Cascades Campus\Document\01_2016.11.14 Engineering Due Diligence Report\Rf_Eng. Due Diligence.docx

Range Development Plan (LRDP) team, to develop recommendations for waste removal and reuse, funding strategies, and next-step recommendations to assist OSU in its evaluation of future campus expansion.

1.1 Site Location

The site is an inactive construction and demolition waste landfill that was previously a pumice surface mine. It is currently owned by Deschutes County and is located in the southwest portion of Bend, Oregon (see Figure 1). The site is bordered to the north and west by residential properties, to the east by commercial development, and to the south by a former surface pumice mine (now owned by OSU), and the current OSU-Cascades campus.

1.2 Background

As shown on Figure 2, the site is 72.4 acres in size and was developed in three distinct areas: Area 1 in the eastern portion of the site (tax parcel 1812060000110 and 181206A000719); Area 2 in the south-center portion of the site (tax parcel 1812060000111); and Area 3 in the western portion of the site (tax parcel 1812060000100). The landfill was operated under an Oregon Department of Environmental Quality (DEQ) solid waste permit (#215) from 1972 to 1996 to dispose of construction and demolition waste, industrial waste, woodwaste, brush, and tires. A previous site investigation conducted by Gershman Brickner & Bratton, Inc. (GBB, 2008) estimated the waste limits (defined herein as waste cell) and composition, in each area. Area 1 is the oldest landfill area and was filled with a large quantity of woodwaste from local saw mills. Area 1 is 23.2 acres; however, the footprint of waste, Cell 1, which extends beyond the western parcel boundary, into property owned by the Bend Park and Recreation District, is estimated to be approximately 24.7 acres. The waste composition in Area 2 is very similar to that of Area 1, except that it also contains construction and demolition debris. Area 2 is 9.8 acres and the waste footprint, Cell 2, is estimated to be 7.1 acres. Area 3 is 39.4 acres and the waste footprint, Cell 3, is estimated to be 19.5 acres. Cell 3 waste includes mill waste, construction and demolition debris, and large woody debris such as logs and stumps¹.

Cells 2 and 3 were closed in 1997. A portion of Cell 1 has been undergoing pyrolysis², and therefore could not receive closure certification by DEQ.

¹ Note that the permit allowed for disposal of industrial waste, but none was specifically identified in the prior investigations (GBB, 2008, Apex 2016).

² Pyrolysis is thermochemical decomposition of organic material at elevated temperatures in the absence of oxygen. R:\1290.01 Oregon State University-Cascades Campus\Document\01_2016.11.14 Engineering Due Diligence Report\Rf_Eng. Due Diligence.docx

2.1 Document Review and Data Gap Analysis

The MFA team reviewed all of the available engineering and environmental documents that have been completed for the landfill. After this review, MFA identified the following environmental data gaps and associated action items:

- Soil gas—historically, soil gas samples have been collected along the perimeter of the Site. Per OSU's site planning, future redevelopment scenarios would involve construction of buildings at the Site. Characterizing soil gas within the landfill footprint would help inform redevelopment decisions and enhance understanding of potential exposure pathways and receptors.
- Landfill cap—anecdotal evidence suggests that much of the landfill cap material was generated on-site. No sampling of the cap material had been performed to assess contaminant levels, if any. Sampling the cap material would help inform redevelopment decisions at the Site.
- Groundwater—groundwater at the Site was sampled in 2013 from three monitoring wells for parameters identified in the DEQ closure permit. Total petroleum hydrocarbons (TPH), specifically diesel-range TPH, has been detected in waste material. Groundwater samples from the Site have not been analyzed for TPH. While it is unlikely that TPH impacts have extended to groundwater, testing to verify the presence or absence of TPH in groundwater would help inform acquisition decisions.
- Asbestos containing materials (ACMs)—potential ACMs were visually observed in refuse at the Site during past investigations. Industry standard practice would be to assume that any potential ACMs encountered should be treated as such.

After the data gap analysis, MFA prepared a field investigation plan to collect and characterize subsurface soil gas and landfill cap material. The purpose of the field investigation was to obtain data of sufficient quality to understand impacts in environmental media, and to evaluate data relative to appropriate risk-based criteria in support of site redevelopment. Evaluation of the groundwater and ACMs were not included in the field investigation study. It was assumed at the time of the investigation that groundwater and ACM will be addressed during acquisition and/or redevelopment activities. A copy of the Data Gaps Summary and Focused Site Investigation Plan is included as Attachment A.

Before site investigation work began, MFA developed a Site Safety and Access Plan that described the recommended practices and procedures to protect the health and safety of MFA team members working on the site. The plan included evaluation of potential hazards at the site, including pyrolysis, safety equipment needed to perform work and air monitoring for LFG exposure.

2.2 Field Investigation

MFA collected multiple subsurface soil vapor and composite soil samples throughout the site. Subsurface soil vapor results collected in Cells 1 and 2 had methane levels at or above the DEQ guidance concentration for methane mitigation for structure and confined space entry. Subsurface soil vapor samples results from Cells 1, 2, and 3 were compared to DEQ risk-based concentrations for urban residential vapor intrusion into buildings. Of the 51 compounds tested, two samples exceeded these criteria for ethylbenzene and three exceeded these criteria for naphthalene. The remaining compounds were below these criteria.

Soil sample results from all cells showed detections of some metals, all of which were within DEQ background concentration for the Bend region, and below DEQ risk-based concentrations for residential use.

Based on these results, future development on the Site would likely involve methane mitigation and vapor intrusion measures incorporated into the redevelopment plan. Existing cap material could be reused as backfill on-site. Field investigation results are included as Attachment B.

2.3 Deschutes County Pilot Study

In the spring of 2016, Deschutes County commissioned a pilot study to assist in the evaluation of potential waste beneficial reuses and revenue. The Draft County Pilot Study Report (Apex, 2016), was prepared and made available to MFA in August 2016. The pilot test data was collected to evaluate whether landfill materials can be segregated in a cost-effective manner; if reduction of waste is possible as a result of segregation and recycling; the process and time required to segregate materials; and processes necessary to prevent nuisance conditions (e.g., dust, odors, noise) and protect public safety and health. Apex also compared its results to those of GBB (GBB, 2008).

The pilot study investigation was focused on an area limited to approximately one-third of Area 1, and equally limited portions of Area 2. This may not provide an accurate representation of the entire waste volume due to its heterogeneous nature. The investigation also excluded the pyrolysis area due to safety concerns. However, cause of combustion and other issues remain a data gap. Estimates of waste quantities in Cells 1 and 2 developed by the pilot study are included in the following tables:

| Operation Period | 1972–1987 | | Est. Max. Waste Depth (ft) | | 60-70 |
|----------------------|------------|-------------|----------------------------|------------|-------------|
| Size (ac) | 23.2 | | Est. Waste Volume (cy) | | 1,133,500 |

Notes: Est. = estimated ac = acres cy = cubic yards Misc. = miscellaneous

The GBB and Apex estimates vary substantially for several materials, possibly due to differing identification methods and definitions. Regardless, the pilot study results suggest a much higher percentage of fine material than the amount of fines estimated in the GBB report. MFA noted that characteristics of the fines were not well defined in relation to the physical properties in the pilot study report. The test pit logs note sawdust as the primary component of the fines; however, there is no analysis to confirm the sawdust component of the fines compared to soil, which would provide critical data for determining beneficial reuse of fines as backfill and cover soil. Photos of the test pits and stockpiles included in the pilot study report appear to have significant amounts of larger wood debris. The calculations suggest the wood component to be only 1.4% in Cell 1 and 3% in Cell 2, is low compared to the visual evidence. After discussing with Apex staff, MFA found that large wood debris broke down into finer material during the mechanical screening process. During the pilot study, excavated material was run twice through a shaker screen before being hauled offsite to be sorted.

The results also suggest the amount of recoverable material is much less than originally anticipated. This information significantly altered MFA's development of remediation scenarios. MFA had originally evaluated the screening and sorting waste at a material recovery facility (MRF), either developed on-site or at an existing regional MRF located off-site, to separate the waste into recyclable materials, reusable materials (e.g., biomass fuel, compost), and rejected materials. However, based on the results of the pilot study, MFA determined that the recovery of reusable and recyclable material may not be feasible, due to the low percentage of recoverable material that would justify the level of effort for marketing.

Due to the variances in estimated waste quantities between the pilot study and GBB reports, MFA has utilized the average of the volumes estimated in both reports to develop remediation scenarios for each landfill area.

3 REMEDIATION SCENARIO DEVELOPMENT

3.1 Initial Remediation Scenarios

MFA initially evaluated developing over waste in its current location in an effort to minimize disturbance to existing conditions. The existing waste in Cells 2 and 3 could be left in place, however Cell 1 will require implementation of other remediation methods due to the presence of pyrolysis in the cell and the regulatory requirement to extinguish the pyrolysis in order to attain final closure. This would require structural ground improvements such as piles or rock columns to stabilize structure and utility foundations from differential settlement and seismic impacts. Developing over existing waste also poses additional risks such as methane exposure and potential for future

pyrolysis. As discussed in Section 2.2, any development will need to account for methane mitigation and vapor intrusion. Given the substantial limitations and based on feedback from the OSU team, it was determined that leaving all waste in place posed too much risk and was not a preferred approach.

MFA also evaluated excavation and hauling waste off-site for disposal at the Knott Landfill in Bend, or at another appropriate disposal facility. MFA assumed an average truck capacity of 24 cy per vehicle (using truck and pup) and estimated hauling all of the waste from the demolition landfill would result in over **101,000 truck trips**. Assuming a fleet of ten trucks, making a total of 40 trips per day, 5 days per week, it would take approximately **10 years** to haul all waste from the site. The Knott landfill currently has available capacity to accommodate most of the waste from the demolition landfill; however, accepting all of the waste from the site would consume the community's existing landfill capacity. Large landfills with greater capacity are available, but the haul distance to these facilities is two to three times farther than the haul distance to the Knott Landfill, resulting in greater environmental impact and cost. Due to hauling costs, landfill tipping fees, and negative impact to Knott Landfill capacity, on top of the projected heavy truck-traffic in local neighborhoods over an extended period of time, this scenario was not considered to be a beneficial remediation alternative.

As previously noted, MFA assessed the potential of screening and sorting waste at a MRF, either developed and located on-site or at an existing regional MRF located off-site, to separate the waste into recyclable materials, reusable materials, and rejected materials. However, the results of the pilot study indicate that the amount of recoverable material available is much less than originally estimated in the GBB report. Based on the results of the pilot study, this option is not an effective option for site remediation.

Based on the findings listed above, our discussions with DEQ, feedback from the OSU team, review of background documents provided by OSU, and field investigations, MFA has refined the following remediation options.

3.2 Waste Removal

Waste could be excavated in full from Cells 1 and 2. Excavated waste would be stockpiled for screening and reuse, or relocated to an expanded Cell 3. Prior to waste removal, the cover soil would be removed and stockpiled on-site for future reuse as backfill. MFA has assumed a waste excavation production rate of 1,300 cy/day per excavator.

As previously noted, Cell 1 cannot receive permitted closure certification through DEQ or be developed until pyrolysis has been addressed. If pyrolysis could be addressed in-situ, development over existing waste would require extensive design elements to mitigate differential settlement effects, long-term monitoring, and maintenance. Therefore, it is assumed that the most favorable option would be to remove all of the waste in Cell 1. During excavation of the waste in Cell 1, the exposed east face may not have a sufficient factor of safety for support of three existing buildings to the east. Shoring, such as soil nails, would need to be installed as excavation proceeds. Reportedly, there are also approximately 3,600 cy of tires landfilled in Cell 1. Once excavated, Oregon Revised

R:\1290.01 Oregon State University-Cascades Campus\Document\01_2016.11.14 Engineering Due Diligence Report\Rf_Eng. Due Diligence.docx

Statute 459.247 prohibits reburying them on-site They would therefore be disposed of at an approved facility.

Cell 2 lies directly adjacent to the existing pumice mine. The most beneficial reuse for Cell 2 would be full removal of waste as it would provide a transitional grade between the pumice mine and the rest of the site.

Cell 3 waste will most likely remain in place. Development of Area 3 as passive uses, such as sports fields, park, or parking lots, could occur on top of existing waste and relocated Cell 1 and Cell 2 waste without requiring major structural ground reinforcement. Development over existing waste would require long-term maintenance and monitoring activities, as described in detail in Section 5.2.

3.2.1 Removing and Processing Pyrolysis Material

The active pyrolysis area in Cell 1 is estimated to be a 75'-wide strip along the entire pumice face, 1,390 feet, on the east side of Area 1. Based on the GBB report, average pyrolysis depth is estimated at 50 feet. Volume of active pyrolysis material is estimated to be 192,700 cy.

Prior to moving excavation equipment onto Cell 1, ground density monitoring would need to be conducted to test for and avoid sinkholes in active working zones. During excavation, temperature surveying would also be needed to identify pyrolysis areas and ensure worker safety. In addition, a fire suppression system would be needed on-site in case of any flare ups. A potential method evaluated for pyrolysis material removal is isolation of the material in smaller confinements utilizing vertical slurry walls (down to a stable former daily cover soils stratum). Slurry walls would be extended down to the bottom of the waste (or to a former cover soil level) to isolate a portion of the pyrolysis material, limiting the pyrolysis work/control area. Water or slurry could then be injected into the isolated area to stabilize and cool the material prior to excavation.

Pyrolysis material is not suitable for reuse such as backfill or compost. Excavated pyrolysis material will be processed to remove moisture and heat, and then relocated to Area 3 for re-landfilling in an expanded cell.

3.3 Waste Screening

MFA's analysis assumes screening of waste after excavation at a screening rate of 1,200 cy/hour. Material waste was screened as part of the pilot study and was twice run through a shaker screen that broke down much of the large wood material into fines. This resulted in the overwhelming majority of waste material in Cells 1 and 2 being reported as fines in the pilot study. To prevent the breakdown of large wood material, MFA proposes screening waste using a less abrasive method, such as a bar screen. Large wood material separated during the screening process would be relocated to Area 3 and consolidated into a single area. This wood material can then later be removed or repurposed as needed by OSU. Waste streams generated by the screening process and disposal methods for each waste stream are shown in Figure 3 - Cell 1 Remediation Approach and Figure 4 - Cell 2 Remediation Approach included at the end of this report.

R:\1290.01 Oregon State University-Cascades Campus\Document\01_2016.11.14 Engineering Due Diligence Report\Rf_Eng. Due Diligence.docx

3.4 Screened Fines Beneficial Reuse

MFA obtained a sample of screened fines from the pilot study excavation and submitted it for agricultural testing. Agricultural testing results included in Attachment C show the material does not contain enough nutrients to be used for composting. The material may be used as a soil amendment, but the low market value for this material would likely provide little to no-net revenue.

MFA has evaluated a potentially viable option of blending the screened fines with soil sourced onsite (i.e., cover soil and excavated native material) and reusing it as backfill throughout the site. The small batch of screened fines obtained from the pilot study have a high organic content (22%), but could be blended with additional soil to produce a backfill material with an organic content suitable for development (approximately 4%³). Based on this limited test, the screened material would require blending with soil at a ratio of 4.5 to 1. At this ratio, there is not enough soil on-site to be able to blend the entire volume of screened fines; however, a different screening method could be developed to reduce the breakdown of the larger wood debris and thereby reduce the screened fines organic content, resulting in a lower soil-to-fines blending requirement. This increases the amount of screened waste that can be used as blended backfill material. The excess screened fines could be used as cell cover soil and topsoil for landscape areas, or relocated to Cell 3. Large wood material separated during the screening process would be relocated to Cell 3 and consolidated into a single area. This wood material can then later be removed or repurposed as needed by OSU.

3.4.1 Materials Management Grant

MFA has assisted Deschutes County, in cooperation with OSU-Cascades, in applying for a materials management grant through DEQ to further explore the opportunity of beneficial re-use of waste at the site. If accepted, the grant would be used to complete a pilot study to test the viability of materials found in the landfill for use as a soil amendment or clean backfill in remediation of the landfill. The study will seek to determine if there is one or more routes to successfully extract, treat, and prepare materials for reuse. Additionally, this study would look into identifying effective methods of screening and sorting waste.

3.5 Relocation of Waste to Expanded Cell 3

Excavated waste could be consolidated on-site to Area 3. Cell 3 sits within a depression and if the cover soil were removed, there would be roughly 450,000 cy of additional airspace capacity. The proposed landfill cell could also be expanded farther beyond the existing waste footprint of Cell 3, but still within the limits of Area 3. Native material could be excavated from this area to create an additional 581,410 cy of storage capacity for waste, and then be used as backfill elsewhere on-site. This would provide a total of 1,031,410 cy of airspace capacity in Area 3, which is enough capacity to facilitate all the waste from Cell 1 and Cell 2 after repurposing a portion of the screened waste for backfill, cover soil, and top soil. Figure 5 – Cell 3 Remediation Approach depicts the options evaluated

³ <u>http://docs.lib.purdue.edu/cgi/viewcontent.cgi?article=2676&context=jtrp</u>

R:\1290.01 Oregon State University-Cascades Campus\Document\01_2016.11.14 Engineering Due Diligence Report\Rf_Eng. Due Diligence.docx

Given the arid condition of the area and deep groundwater elevations, a bottom liner and leachate collection system should not be necessary as part of the expansion of the existing landfill cell. MFA discussed this approach with DEQ as the remediation alternatives were refined (see DEQ Notes included as Attachment D).

Maintaining a landfill cell on-site will require LFG monitoring, and long-term maintenance. Limited groundwater monitoring is also anticipated. It could also put some restrictions on future development over the waste footprint. Additional structural and ground improvements may be needed to support structures. Also stormwater facilities should be constructed outside of the waste footprint or otherwise designed to avoid infiltration and leachate generation. Monitoring requirements are discussed further in Section 5.2.

4 REGULATORY REQUIREMENTS

4.1 Regulatory process strategy

MFA has discussed the landfill's history, closure, and regulatory requirements in association with redevelopment with DEQ Solid Waste engineer, Joe Gingerich, P.E. Mr. Gingerich indicated that DEQ envisions all remediation and redevelopment work would be completed under the existing Solid Waste Disposal Site Closure Permit (No. 215). Mr. Gingerich also noted that DEQ would require pyrolysis in Cell 1 to be addressed through excavation or other means. This remediation and redevelopment work could be incorporated into the DEQ's Prospective Purchaser Agreement (PPA) process, if desired by OSU.

The MFA team developed a summary of the closure and post-closure regulatory requirements for the various remediation and reuse strategies. Specific tasks will include the following:

- Identify significant benefits or challenges that may exist for obtaining permits to allow certain activities, such as mining of waste, to reclaim, recycle, or dispose of materials.
- Coordinate with DEQ solid waste and environmental cleanup program staff to identify landfill monitoring, maintenance, and administration requirements that could be streamlined as allowed by the nature of the demolition landfill (primarily woodwaste and demolition/construction debris) or by specific developed features.
- Detail the PPA process, specific to site conditions and identified options. Establish risk-control mechanisms.
- Draft a report that summarizes the local, state, and federal regulations for air quality, water quality, and solid waste and stormwater management that apply to the various remediation and reuse scenarios. The report will contain permitting timelines to show how the processes overlie site-development schedule requirements.
- Deliverables:

- Notes from meetings with DEQ
- o Regulatory process strategy technical memorandum
- Requirements for long-term monitoring

4.2 Long-Term Monitoring Requirements

Leaving the waste in place poses some risks, such as differential settlement, methane gas exposure, and the potential of future pyrolysis (if not addressed through remediation). To address these potential risk factors, the following elements would likely be required for buildings constructed over waste:

- A LFG barrier under building slabs (geotextile or liquid membranes).
- LFG venting systems below floor slabs.
- Long-term methane monitoring for internal building and exterior spaces.
- Long-term structural monitoring for differential settlement.
- Subsurface temperature monitoring.
- Long-term groundwater monitoring.

For open spaces where waste is present, the following elements would likely be required:

- LFG extraction and venting systems.
- Long-term LFG perimeter and surface monitoring.
- Long-term site monitoring (inspections, LFG measurements).
- Long-term physical cap and surface maintenance (settlement, vegetation management, etc.).
- Long-term groundwater monitoring.
- Subsurface temperature monitoring.

LFG, pyrolysis, and differential settlement are the primary concerns for short- and long-term development scenarios. Due to the arid climate and deep groundwater, leachate control is not likely a concern for this site.

5 PHASING AND SCHEDULING

MFA has developed a remediation phasing plan to align with projected funding availability. Remediation of the site is anticipated to be complete in three phases, as described below. Each phase could be completed within two years. See Figure 6 – Remediation and Reclamation Phasing for a depiction of the phasing areas.

Phase 1 would include remediation of the southern four acres of Area 1. The remediation would include excavation of approximately 18% of the total waste in Cell 1. All of the excavated waste

would be screened, processed to address pyrolysis, and stockpiled. The wood waste and processed pyrolysis material would be re-landfilled in Cell 3 within the existing waste footprint. This phase assumes that all of the documented tires (3,400 cy) would be removed and disposed of off-site. Screened waste would be blended with cover soil from Cell 3 and backfilled into Area 1 to a desired finish grade. This would create approximately four acres of developable land in Area 1. There would be a surplus of waste screenings, approximately 92,400 cy, which could be blended with loose material that exists in the pumice mine and cover soil from Cell 3 to create 508,00 cy (assuming a 4.5:1 mixing ratio as described in section 3.4 above) for placement in the reclamation of the pumice mine. The projected cost for the remediation of this phase is approximately \$5.7M (see Attachment E).

Phase 2 would include the remediation of the entirety of Cell 2. Approximately 135,000 cy of waste would be screened to prepare 113,500 cy of it for blending with soil to create suitable backfill for use in the pumice mine; and the remainder would be used for cell cover soil and landscaping topsoil. The wood waste and non-screened waste would be re-landfilled in Cell 3 within the existing waste footprint. In addition to the remediation of Cell 2, this phase also involves the reclamation of the remaining pumice mine. The activities would include the excavation of an additional 370,000 cy beyond the excavation of Cell 2. The phase would also include embankment and compaction of 624,000 cy (containing 113,500 cy of screened waste) to a desired finish grade. This would create approximately 21.6 acres (9.8 in Area 2 and 11.8 in the pumice mine) of unencumbered. The projected cost for the remediation and reclamation of this phase is approximately \$11.8M (see Attachment E).

Phase 3 would include remediation of the remaining 19.2 acres of Area 1. The remediation would include excavation of the remaining 82% of the total waste in Cell 1. 160,450 cy of the excavated waste would be screened and stockpiled for beneficial reuse. The wood waste, processed pyrolysis material, and un-screened waste would be placed in Cell 3. Screened waste would be blended with cover soil from Cell 1 and soil from Cell 3 and then backfilled into Area 1 to a desired finish grade. This would create an additional 19.2 acres of developable land in Area 1. The projected cost for the remediation of this phase is approximately \$25.6M (see Attachment E).

D REMEDIATION COSTS

The MFA team utilized results of the initial site analysis to develop remediation costs for the multiple redevelopment scenarios. Using the iterative design process, MFA refined the remediation alternatives in collaboration with the OSU team, incorporating feedback received at design charrettes, and prepared opinion of probable costs for each scenario.

MFA prepared budgetary-level cost estimates for remediation of each cell, which are included in Attachment E. In developing these cost estimates, MFA assumed a 15% contingency to account for design of remediation, monitoring during construction, and reflect unknown conditions (such as

adverse weather conditions, material cost variances, or unfavorable market conditions). It is assumed that approximately 3% of all waste is not amenable to processing or on-site relocation and will need to be hauled off-site for disposal in an appropriate landfill. For the purposes of remediation cost estimating, we have assumed that the cost of disposal of the rejected material will be paid for by a party other that OSU.

Costs associated with recycling of metal materials are not included in the cost estimate. It is assumed that material's reuse preparation process and associated sales revenue are net zero items. Due to the low market value, no revenue was assumed for sale of the screened fines as soil amendment material.

A summary of budgetary-level remediation cost estimates is provided below:

| Phase 1 | \$5.7 M |
|---------|----------|
| Phase 2 | \$11.8 M |
| Phase 3 | \$25.6 M |
| Total | \$43.1 M |

Table 4-1Budget-Level Remediation Cost Estimate

7 FUNDING STRATEGIES

MFA has collaborated with OSU-Cascades to identify potential grant sources from state and federal agencies, as well as funding through direct state appropriations. Potential grant sources are summarized in the Funding Strategy memorandum included as Attachment F.

Based on the results of the engineering due diligence and remediation scenario development described in this report, MFA has demonstrated that the existing landfill can be repurposed to benefit the community and improve the environmental quality of the encumbered site. MFA evaluated the option of hauling waste off-site to the Knott Landfill, but determined that this alternative generated negative impacts to the local community by significantly increasing truck-traffic

(over 101,000 truckloads) over an extended period of time and eliminating the municipal landfill capacity for local waste disposal.

MFA recommends managing waste on-site and utilizing screened material as backfill for the site or adjacent pumice mine. This approach will reduce environmental impacts and consolidate the total waste at the site to a smaller footprint, which minimizes long-term maintenance and monitoring efforts, and also provides more flexible campus development opportunities.

These options are consistent with OSU sustainability objectives and will likely provide research and educational opportunities to the University.

The services undertaken in completing this report were performed consistent with generally accepted professional consulting principles and practices. No other warranty, express or implied, is made. These services were performed consistent with our agreement with our client. This report is solely for the use and information of our client unless otherwise noted. Any reliance on this report by a third party is at such party's sole risk.

Opinions and recommendations contained in this report apply to conditions existing when services were performed and are intended only for the client, purposes, locations, time frames, and project parameters indicated. We are not responsible for the impacts of any changes in environmental standards, practices, or regulations subsequent to performance of services. We do not warrant the accuracy of information supplied by others, or the use of segregated portions of this report.

July 20, 2016 Project No. 1290.01.01

Kelly Sparks Associate VP Finance and Strategic Planning Oregon State University - Cascades 497 SW Century Drive, Suite 105 Bend, Oregon 97702

Re: Demolition Landfill Reclamation—Data Gaps Summary and Focused Site Investigation Plan

Dear Ms. Sparks:

Oregon State University - Cascades (OSU-C) is conducting due diligence efforts in anticipation of the acquisition of the former Demolition Landfill properties located in Bend, Oregon (the Site) (see Figure 1). The Site is comprised of four tax lots and includes approximately 76 acres of land in Deschutes County (the County). The landfill comprises three cells (Areas 1 through 3) (see Figure 2); various historical environmental investigations have been conducted in all three areas, with the primary focus being Area 1. The framework for characterizing environmental data gaps at the former Demolition Landfill is presented below.

BACKGROUND

The Site is currently an inactive construction- and demolition-waste landfill that was developed at a former pumice surface mine. Area 1, the easternmost landfill cell, was the oldest area where landfilling took place and was filled with a large quantity of woodwaste from local saw mills. Most of the landfill was closed in 1997; however, Area 1 has not been closed because it is undergoing pyrolysis. Subsurface temperature changes, landfill-gas production, and groundwater monitoring are ongoing at the Site. Various environmental investigations have been conducted at the Site and are summarized below.

In 2002, URS Corporation (URS) provided the County with a redevelopment study for the Site. The purpose of the report was to convey site conditions to the County and to identify possible reuse. The report reviewed then-current vegetation, zoning, available utilities in the area, transportation considerations, and nearby water rights, as well as a groundwater beneficial use survey. The report included a property evaluation and identified potential reuse scenarios, such as a golf course (URS, 2002).

Project No. 1290.01.01

Kelly Sparks July 20, 2016 Page 2

In 2008, because there was considerable interest in redeveloping the Site, Gershman, Brickner & Bratton, Inc. (GBB) provided the County a summary of completed site investigations as well as performed additional site assessment activities. The County's goal was to provide as much information as possible about the Site to prospective developers (GBB, 2008). The report also provided a summary of the 1997 David Evans & Associates, Inc. (DEA) subsurface assessment performed for the County.

According to GBB, the primary focus of the 1997 investigation was the assessment of Area 1. Test pits TP1 through TP9, ranging from 3 feet to 21 feet below ground surface (bgs), were advanced. Twenty-eight borings (B1 through B28), ranging from 5.5 feet to 34.5 feet bgs, were advanced, meeting with refusal in some instances. Eight deeper borings were also advanced (B29 through B36). According to GBB, this assessment provided information on waste thickness; however, the exploration pattern was spotty and included only minor analysis of soil and gas (and those data were not available for Maul Foster & Alongi, Inc.'s [MFA's] review). This assessment also identified the issue of pyrolysis associated with the anaerobic decomposition of woodwaste in the landfill.

It appears that subsurface temperature and landfill-gas monitoring locations were established in 1997; however, data from those also were unavailable for review, and it is unknown if those locations still exist.

In 2008, GBB conducted additional subsurface investigation activities to supplement the 1997 investigation and provide more information on the composition of the waste and the potential for impacts to the native material below the landfill. GBB completed full-depth drilling into waste and underlying soils; this included 13 exploratory borings (B37 through B49) and 14 shallow test pits (TP10 through TP23; up to 20 feet bgs), as well as replacement of three landfill-gas wells and three temperature probes originally installed by DEA in 1997.

Test pits were advanced primarily to identify waste composition and materials. Waste consisted primarily of ash, sawdust, metal, tires, woodwaste, roofing materials, and fill/fines. In addition, potential asbestos-containing materials (ACMs) were observed in a few test pits. GBB also performed a subsurface magnetic and electrical resistivity survey to understand waste thicknesses.

Waste and underlying soils from borings were sampled and analyzed for metals, total petroleum hydrocarbons (TPH), volatile organic compounds (VOCs), semivolatile organic compounds, polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls, and pesticides/herbicides, in addition to moisture and organic content. The analytical results were screened against Oregon Department of Environmental Quality (DEQ) risk-based criteria (RBCs) established at the time (July 2007); results are as follows:
Kelly Sparks July 20, 2016 Page 3

- Area 1
 - Generally, waste from borings B38 through B41 and MW2 contained TPH, VOCs (specifically benzene and tetrachloroethylene), the PAH benzo(a)pyrene, and metals arsenic and lead above residential RBCs. Benzene concentrations observed in B38 (condensate) were above the residential vapor intrusion RBC.
 - Two native soil samples (B40 and B42) had arsenic above residential RBCs.
- Area 2
 - Waste from B37 had diesel-range TPH above residential RBCs (22,400 parts per million). The report indicated that this result could be due to matrix interference. Soils exhibited elevated PAHs, arsenic, and lead above residential RBCs.
- Area 3
 - Waste from B48 had the VOC trichloroethylene at ten times the residential leaching-to-groundwater RBC. Samples from B45 and B48 had arsenic above residential RBCs.

Some chemicals were identified in some of the waste materials; however, it does not appear that waste constituents have impacted the underlying soils. In addition, the waste material does not appear to be hazardous (GBB, 2008). GBB concluded that the deepest point of waste in the landfill is more than 200 feet above the static groundwater level, and infiltration to the soil below the landfill was not indicated. General flow of groundwater was assumed to be northeast; however, this interpretation was not based on data collected from monitoring wells.

In 2013, completing work for the County (the current site owner), PBS Engineering + Environmental (PBS) advanced three deep borings (ranging from 265 feet to 315 feet bgs), which were completed as monitoring wells (MW-1 through MW-3) in March and April 2013. Groundwater was encountered between 242 and 293 feet bgs at the Site and, based on depth-to-water measurements taken at the time, groundwater flow is interpreted to be east-northeast. Groundwater is located approximately 150 feet below fill waste and is not in contact with landfill materials. Groundwater monitoring was completed in accordance with the DEQ solid waste closure permit number 251. Analytical results show a closure permit exceedance for pH in groundwater from two of the three monitoring wells (MW-2 and MW-3). Arsenic, barium, chromium, vanadium, and zinc were detected in one or more monitoring wells but at concentrations below U.S. Environmental Protection Agency (USEPA) maximum contaminant levels and DEQ guidance levels. Additionally, PBS visually assessed the active pumice mine south adjacent to the Site to interpret the subsurface geology

Kelly Sparks July 20, 2016 Page 4

within the uppermost 100 feet. Rock coring was completed (BH-1) at the Site to 260 feet bgs and a site geologic interpretation of the volcanoclastic material was provided (PBS, 2013a).

In October 2013, PBS completed a Phase I environmental site assessment (ESA) for two properties owned by OSU-C that are adjacent south and west of the Site. At the time, these properties were referred to as the Chandler and Robinson properties. The ESA identified no recognized environmental conditions pertaining to the properties but indicated that the adjacent landfill cap extended onto the properties and recommended an investigation to understand if landfill material was present (PBS, 2013c). Based on the recommendation, PBS completed a focused subsurface investigation of two properties located south adjacent to the Site. Test pits advanced along the property boundary to delineate the waste material/native soil boundary confirmed that solid waste material extends approximately 20 feet south from the northern edge of the Chandler property and approximately 340 feet laterally along the boundary. Solid waste was not observed to extend onto the Robinson property (PBS, 2013b).

In 2014, Apex Companies, LLC (Apex) completed a geoenvironmental conditions summary for development of mitigation alternatives for future redevelopment at the Site. Apex identified four primary site redevelopment constraints: areas that contain significant landfill material; areas where low temperature subsurface combustion may occur; requirements of the DEQ solid waste permit pertaining to the Site; and migration/impacts to the surrounding community, including fugitive odors and trucking impacts. Many alternatives and approaches were identified, including avoidance of landfilled areas during redevelopment, and excavation and reconsolidation of landfill materials in other cells at the Site (Apex, 2014).

Refer to Figure 2 for historical sampling locations and features of interest.

DATA GAPS

Based on the above summary of data and review of historical sampling and analysis completed at the Site, MFA has identified the following data gaps:

- Soil gas—historically, soil gas samples have been collected along the perimeter of the Site. Future redevelopment scenarios may involve construction of buildings on top of the Site. Characterizing soil gas from the footprint of the landfill may help inform redevelopment decisions and enhance understanding of exposure pathways and receptor potential.
- Landfill cap—anecdotal evidence suggests that much of the landfill cap material was generated from the Site. The cap material has not been sampled to understand if it has been impacted by metals or other activities at the Site. Sampling the cap material may help inform redevelopment decisions at the Site. Cap thickness is variable at the Site.

Project No. 1290.01.01

Kelly Sparks July 20, 2016 Page 5

- Groundwater—groundwater at the Site was sampled in 2013 from three monitoring wells for parameters identified in the DEQ closure permit. TPH, specifically diesel-range TPH, has been detected in waste material. Groundwater samples from the Site have not been analyzed for TPH. While it is unlikely that TPH impacts have extended to groundwater, no testing to verify the presence or absence of TPH in groundwater has been completed.
- ACMs—potential ACMs were visually observed in refuse at the Site during past investigations. The presence of ACMs in refuse at the Site is likely, and industry standard practice would be to assume that any potential ACMs encountered should be treated as ACMs.

PURPOSE AND OBJECTIVES

The purpose of this focused site characterization is to generate data of sufficient quality to understand impacts in environmental media, to evaluate data relative to appropriate RBCs, and to support site redevelopment. The approach and methods are intended to support the following project objectives:

- Evaluation of potential risk to current and likely future receptors on the Site
- Evaluation of potential cleanup options/engineering controls for impacted media at the Site

The activities outlined in this plan are designed consistent with DEQ guidance concerning Risk-Based Decision Making for the Remediation of Petroleum-Contaminated Sites (DEQ, 2003).

SCOPE OF WORK

MFA proposes sampling of subsurface soil gas and landfill cap material for chemicals of interest. Note that not all data gaps identified are being addressed in this assessment (i.e. groundwater and ACM). In the event that OSU-C moves forward with acquisition, groundwater would likely be addressed as part of a Prospective Purchaser Agreement, and ACM would be addressed during acquisition and/or redevelopment activities.

Proposed sampling locations are shown on Figure 3. Soil-gas sampling locations were chosen based on elevated analytical results for chemicals of interest from previous investigations. Additionally, one boring will be advanced in Area 3 to confirm cap thickness in this area (see Figure 3)¹.

¹ Historical investigations have logged cap thickness up to 45 feet in this vicinity.

Kelly Sparks July 20, 2016 Page 6

Soil-Gas Sampling

Public and private utility-locating services and other information sources will be used to check for underground utilities before work begins. MFA will coordinate fieldwork to locate possible on-site utilities and piping or other subsurface obstructions.

Soil-gas samples will be collected from temporary boreholes in up to six locations, as shown on the attached Figure 3. The borings will be advanced by Pacific Soil and Water of Tigard, Oregon, with oversight provided by an MFA geologist registered in Oregon or a geologist or engineer working under the supervision of a geologist registered in Oregon.

The soil borings will be advanced using a Geoprobe[™] direct-push drilling unit. A "Post Run Tubing" (PRT) system will be used to eliminate problems that may occur with sampling directly through the steel rods. See Figure 4 for sample system configuration. The PRT system uses an adapter and tubing to isolate the landfill-gas sample from the drill rods, thereby eliminating possible leaks of ambient air from the rod joints into the sample. A PRT point holder and expendable point are attached to the leading end of a sampling screen, and the drill rods will be advanced to the desired depth. Sample depths are anticipated to be between 5 and 15 feet, making sure to target material below the existing cap, when possible. The PRT adapter attached to the sample tubing is threaded into the reverse thread fitting in the top of the point holder. The rods will be retracted to release the expendable point, exposing the screen, and creating an opening where landfill gas can enter the PRT. The upper end of the tubing will be connected to the purging/sampling system. A flow controller will be attached to the sample setup to regulate the flow of landfill gas into the sample container. The line will be purged for at least one minute or a period of time sufficient to achieve a purge volume that equals at least three pore volumes, and then the sample will be collected. Helium will be contained in a small tent-like structure that is set up around the sampling apparatus and sampling location, and will serve as a leak-check compound. A helium test will be conducted, using a hand held helium meter, to verify the integrity of the sampling system before the landfill-gas sample is collected for laboratory analysis.

Soil gas samples will be analyzed for the following landfill-gas constituents:

- VOCs by USEPA Method TO-15
- Helium by American Society for Testing and Materials D1946
- Field screening for methane, hydrogen sulfide, helium, and VOCs, using portable meters

Pace Analytical Services, Inc., of Minneapolis, Minnesota, will provide a 6-liter, stainless steel canister (Summa© canister) for each sample. MFA will coordinate with the laboratory to

Kelly Sparks July 20, 2016 Page 7

obtain the lowest possible method reporting limits and to screen concentrations against appropriate DEQ RBCs.

Landfill Cap Material Sampling

Cap-material sampling will consist of 30-point composite samples from each landfill area (see Figure 3). The sampling will incorporate the more statistically sound Interstate Technology & Regulatory Council's (ITRC) incremental sampling methodology (ISM) guidance (ITRC, 2012), to obtain consistent and reproducible analytical results. ISM is a structured composite sampling and processing procedure that provides a reasonable, unbiased estimate of mean contaminant concentrations in a targeted area, i.e., decision unit (DU). Within a DU, increments of soil are collected and composited into one sample container. The laboratory then processes the samples according to methods described in the ITRC guidance (ITRC, 2012).

For ISM, DUs are typically determined based on current and previous site uses. The Site historically was used for mining and landfilling; however, because of the site size as well as the use of these data to inform the need for a contaminated-media management plan, the Site was divided into three DUs, one corresponding to each landfill area identified at the Site (see Figure 3). Consistent with ISM methodology, 30 randomly selected soil increments will be collected from the surface to 6 inches bgs in each DU and then composited into one sample, providing one soil sample from each DU (see Figure 3 for approximate ISM soil sample locations²). The sample from DU 1 will be collected in triplicate and tested to determine variability in results. Soil will be collected for each composite sample (approximately 34 to 68 grams per increment). Samples will be located, prepared, handled, and documented as follows:

- Soil-sampling equipment will be decontaminated before it is used for each sample.
- The increments to be sampled, identified in Figure 3, will be programmed into a global positioning system (GPS) device with submeter accuracy.
- Each increment in the DU will be sampled using a stainless steel sampling device. Once the increment location is identified using GPS, the sample will be obtained. New, disposable gloves will be used for the collection of each sample.
- Approximately 34 to 68 grams of soil will be collected per increment. If coarsegrained particles are encountered, an adjacent location may be sampled.

² In the event that a chosen sample location is not accessible (i.e. surface is covered in asphalt), the location will be field-adjusted and surveyed with a handheld GPS device.

Project No. 1290.01.01

Kelly Sparks July 20, 2016 Page 8

- Soil from each DU will be placed in a laboratory-provided, 1-gallon glass jar, using a gloved hand or a decontaminated stainless steel spoon or trowel.
- Coarse-grained particles (larger than 0.25 inch) may be removed before the sample is placed in a laboratory-supplied container.
- Filled containers will be labeled, packed in iced shipping containers with chain-ofcustody (COC) documentation, and delivered to the contract laboratory.
- Sampling information will be recorded in a field notebook or on a field sampling data sheet, as well as on the COC form.

Analytical quality control requires collection of one triplicate ISM sample per sampling event. The triplicate ISM sample will be collected from the DU in landfill Area 1.

Apex Laboratories, LLC, of Portland, Oregon, will complete the ISM sample processing and analysis for Resource Conservation and Recovery Act 8 metals (arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver) by USEPA Method 200.7/6010.

MFA will receive the data electronically from the laboratory and the data will be transferred to an EQuISTM database. The data will be validated consistent with DEQ and USEPA protocols. To document data reliability, a memorandum will be prepared summarizing evaluation procedures, the usability of the data, and deviations from specific field and/or laboratory methods.

REPORTING

A brief letter report, presenting analytical results of the soil gas and soil sampling with a comparison to DEQ RBCs, will be developed to inform redevelopment approaches.

Sincerely,

Maul Foster & Alongi, Inc.

Merideth D'Andrea, RG Senior Geologist

Re: Demolition Landfill Reclamation—Focused Site Investigation Results

Dear Ms. Sparks:

Oregon State University–Cascades (OSU-C) is conducting due diligence efforts in anticipation of the acquisition of the former Demolition Landfill properties located in Bend, Oregon (the Site) (see Figure 1). The Site is comprised of four tax lots and includes approximately 72.4 acres of land in Deschutes County (the County). The landfill comprises three cells (Areas 1 through 3) (see Figure 2); various historical environmental investigations have been conducted in all three areas, with the primary focus being Area 1. Maul Foster & Alongi, Inc. (MFA) has prepared this letter on behalf of OSU-C describing the results of an investigation which included evaluation of the existing landfill cap material as well as potential landfill gas in soil at the Site. The work has been completed in support of landfill closure and redevelopment activities.

The purpose of the investigation was to assess landfill cap material and whether landfillrelated compounds, including methane- and non-methane-related volatile organic compounds (VOCs) are present in soil gas at the Site. The scope of work is described in the investigation work plan (MFA, 2016).

BACKGROUND

The Site is currently an inactive construction- and demolition-waste landfill that was developed at a former pumice surface mine. Area 1, the easternmost landfill cell, was the oldest area where landfilling took place and was filled with a large quantity of wood waste from local saw mills. Most of the landfill was closed in 1997; however, Area 1 has not been closed because it is undergoing pyrolysis (see high hazard area in Figure 2). Subsurface temperature monitoring and groundwater monitoring are ongoing at the Site. Various environmental investigations have been conducted at the Site and a full summary is provided in the work plan (MFA, 2016).

SAMPLING AND ANALYSES

Consistent with the work plan, six borings were advanced to evaluate soil gas and composite surface samples were collected to assess landfill cap material at the Site. In addition, one

Project No. 1290.01.01

Kelly Sparks November 9, 2016 Page 2

boring was advanced to assess the thickness of the cap material in an area where historical investigations had shown the greatest thickness. Soil-gas boring locations were chosen based on historical sample locations and lateral distribution across the three identified areas at the Site. Sample locations are presented on Figure 2.

Landfill Cap Evaluation

Surface cap material on the Site was sampled using incremental sampling methodology (ISM). ISM is a structured composite-sampling protocol that reduces data variability and provides a reasonable, unbiased estimate of mean contaminant concentrations in a targeted area (i.e., a decision unit [DU]). Within each DU, increments of soil are collected and composited into one sample for laboratory analysis. Each DU sample was comprised of 30 approximately equal increments collected from sample locations placed randomly over a grid. DU1's composite sample was collected in triplicate to comply with the quality assurance protocol of the sampling method. Incremental soil samples were prepared by collecting multiple increments of soil, typically weighing approximately 20 grams, from a specified sample point within the DU and physically combining these increments into a single composite sample. Soil samples were collected within the top six inches of the soil with a stainless-steel hand trowel, which was decontaminated between DUs.

Figure 2 depicts the Site's three DUs as well as individual ISM sample points. The DUs were selected (in general) based on each DU corresponding with a separate landfilled area. Composite soil samples from each DU were analyzed by Apex Laboratories, LLC of Portland, Oregon for the following constituents:

• Resource Recovery and Conservation Act priority pollutant metals (arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver) by U.S. Environmental Protection Agency (USEPA) Method 6020.

Soil Gas Evaluation

Landfill soil gas samples were collected from six temporary boreholes (soil gas monitoring wells B1 through B6) screened from approximately 5.0 feet to 10.0 feet below ground surface (bgs) (see Figure 2). Boring logs for the soil gas sample points are included as Attachment A. Soils observed in boring B1 through B6 indicate cap-thickness ranges from 0.5 feet to 5.0 feet. Additionally, boring B7 was advanced to confirm cap thickness in Area 3, where past investigations had observed a thicker presence of cap material. Soil observations at boring B7 show a cap thickness of approximately 40 feet in the vicinity of that boring (see Figure 2 and Attachment A).

The borings were advanced by Pacific Soil & Water of Tigard, Oregon with oversight provided by MFA. The soil borings were advanced using a truck-mounted GeoprobeTM 6600 direct-push drilling unit. A "Post Run Tubing" (PRT) system was used to eliminate problems related to sampling directly through the steel rods. The PRT system uses an adapter and

Kelly Sparks November 9, 2016 Page 3

tubing to isolate the landfill gas sample from the drill rods, thereby eliminating possible leaks of ambient air from the rod joints into the sample. Boring logs are included as Attachment A. Helium served as a leak-check compound and a helium test was conducted using a hand-held helium meter to verify the integrity of the sampling system before the landfill gas sample was collected. The samples were collected under a helium shroud to detect leaks in the collection system.

Samples were analyzed for the following landfill gas constituents:

- Fixed gases including methane, carbon dioxide, carbon monoxide, nitrogen, and oxygen by USEPA Method 3C, and
- VOCs by USEPA Method TO-15.

Pace Analytical of Minneapolis, Minnesota supplied a 1.5-liter, stainless-steel canister (Summa© canister) for each sample. Samples were also field-screened to evaluate soil gas concentrations during fieldwork. Soil gas was field-screened using a four gas meter (QRAE II), a hydrogen sulfide meter (Jerome 631X), and a photoionization detector (Mini RAE).

MFA received the data electronically from the laboratory and the data was validated consistent with Oregon Department of Environmental Quality (DEQ) and USEPA protocols. The analytical data and laboratory reports are included as Attachment B. A data validation memorandum is included as Attachment C. The data are considered acceptable for their intended use, with the appropriate data qualifiers assigned.

RESULTS

Surface soil composite samples were collected from the three DUs at the Site. Soil analytical data is presented in Table 1. The results show detections of arsenic, barium, cadmium, chromium, lead, and silver in some samples, however at concentrations that are below DEQ risk-based concentrations (RBCs) for residential use as well as within DEQ background concentrations for the Bend region.(see Table 1). Soil cap thickness ranged from approximately 0.5 feet to 5.0 feet thick in borings B1 through B6. Cap thickness in the vicinity of B7 is approximately 40 feet (see Attachment A).

Soil gas was field screened for the presence of landfill gases and VOCs. Table 2 presents field-screening results. Soil gas samples were collected from six locations (B1 through B6) at depths ranging from 5.0 feet bgs and 10.0 feet bgs. Soil gas analytical results are shown in Table 3.

Methane was not detected in soil gas collected from borings B3 and B6. Methane concentrations in the remaining four borings ranged from 1.2 percent (B2) to 10.8 percent (B5) (see Table 3). DEQ guidance requires concentrations above 1.25 percent methane in

Kelly Sparks November 9, 2016 Page 4 Project No. 1290.01.01

confined spaces or structures to be remediated and methane mitigation will be needed during redevelopment at the Site. VOCs were detected in all samples; however only two VOCs, ethylbenzene and naphthalene, were detected at concentrations exceeding their respective DEQ RBCs for urban residential vapor intrusion into buildings (in borings B1, B2, B4, and B5; see Table 3). VOC concentrations in B3 and B6 were below DEQ RBCs.

Based on this evaluation, in the event the Site is redeveloped, the potential for vapor intrusion and methane migration will have to be considered and mitigation potentially incorporated into the redevelopment plan.

Sincerely,

Maul Foster & Alongi, Inc.

hino

Result values in **bold** font indicate a detection.

Shaded results indicate DEQ RBC exceedance.

DEQ = Oregon Department of Environmental Quality.

J = Result is an estimated value.

 ug/m^3 = micrograms per cubic meter.

NV = no value.

RBC = Risk-Based Concentration for Individual Chemicals (DEQ, November 1, 2015).

U = Result not detected at or above method detection limit.

^aSum of m,p- and o-xylenes.

LABORATORY ANALYTICAL RESULTS

Pace Analytical Services, Inc. 1700 Elm Street - Suite 200 Minneapolis, MN 55414 (612)607-1700

August 29, 2016

Stacy Frost Maul Foster & Alongi, Inc 400 East Mill Plain Boulevard Vancouver, WA 98660

RE: Project: 1290.01.01 OSU Cascades- Rev. Pace Project No.: 10357548

Dear Stacy Frost:

Enclosed are the analytical results for sample(s) received by the laboratory on August 02, 2016. The results relate only to the samples included in this report. Results reported herein conform to the most current TNI standards and the laboratory's Quality Assurance Manual, where applicable, unless otherwise noted in the body of the report.

This report was revised to revise the sample qulifier for 10357548006

If you have any questions concerning this report, please feel free to contact me.

Sincerely,

Carolynne That

Carolynne Trout for Joanne M Richardson joanne.richardson@pacelabs.com Project Manager

REPORT OF LABORATORY ANALYSIS

QUALIFIERS

Project: 1290.01.01 OSU Cascades- Rev.

Pace Project No.: 10357548

DEFINITIONS

DF - Dilution Factor, if reported, represents the factor applied to the reported data due to dilution of the sample aliquot.

ND - Not Detected at or above adjusted reporting limit.

J - Estimated concentration above the adjusted method detection limit and below the adjusted reporting limit.

MDL - Adjusted Method Detection Limit.

PQL - Practical Quantitation Limit.

RL - Reporting Limit.

S - Surrogate

1,2-Diphenylhydrazine decomposes to and cannot be separated from Azobenzene using Method 8270. The result for each analyte is a combined concentration.

Consistent with EPA guidelines, unrounded data are displayed and have been used to calculate % recovery and RPD values.

LCS(D) - Laboratory Control Sample (Duplicate)

MS(D) - Matrix Spike (Duplicate)

DUP - Sample Duplicate

RPD - Relative Percent Difference

NC - Not Calculable.

SG - Silica Gel - Clean-Up

U - Indicates the compound was analyzed for, but not detected.

N-Nitrosodiphenylamine decomposes and cannot be separated from Diphenylamine using Method 8270. The result reported for each analyte is a combined concentration.

Pace Analytical is TNI accredited. Contact your Pace PM for the current list of accredited analytes.

TNI - The NELAC Institute.

LABORATORIES

PASI-M Pace Analytical Services - Minneapolis

SAMPLE QUALIFIERS

Sample: 10357548006

[1] The internal standard recoveries associated with this sample exceed the lower control limit for EPA Method TO-15. Results confirmed by second analysis.

ANALYTE QUALIFIERS

CH The continuing calibration for this compound is outside of Pace Analytical acceptance limits. The results may be biased high.

RE: OSU Cascades / 1290.01.01

Enclosed are the results of analyses for work order <u>A6H0076</u>, which was received by the laboratory on 8/1/2016 at 11:00:00AM.

Thank you for using Apex Labs. We appreciate your business and strive to provide the highest quality services to the environmental industry.

If you have any questions concerning this report or the services we offer, please feel free to contact me by email at: <u>pnerenberg@apex-labs.com</u>, or by phone at 503-718-2323.

DATA VALIDATION MEMORANDUM

DATA QUALITY ASSURANCE/QUALITY CONTROL REVIEW

PROJECT NO. 1290.01.01 | NOVEMBER 9, 2016 | OREGON STATE UNIVERSITY, CASCADES CAMPUS

Maul Foster & Alongi, Inc. (MFA) conducted an independent review of the quality of analytical results for the demolition landfill, and potential Oregon State University Cascades Campus site in Bend, Oregon. Six soil gas samples and eleven soil samples were collected. Ten of the soil samples were comprised of soil increments composited using incremental sampling methodology (ISM) procedures by the laboratory, as described in the Oregon Department of Environmental Quality-approved (DEQ) incremental sampling plan (DEQ, 2012). The samples were collected on July 29, 2016.

Apex Laboratories, LLC (Apex) and Pace Analytical (Pace) performed the analyses. Report numbers A6H0076 and 10357548 were reviewed. ISM samples were processed by Apex. The analyses performed and samples analyzed are listed below.

| Analysis | Reference |
|-----------------------------------|----------------|
| Fixed Gases | USEPA 3C Gases |
| Total Metals | USEPA 6020A |
| Volatile Organic Compounds (VOCs) | USEPA TO-15 |

USEPA = U.S. Environmental Protection Agency.

DATA QUALIFICATIONS

Analytical results were evaluated according to applicable sections of USEPA procedures (USEPA, 2014) and appropriate laboratory and method-specific guidelines (Apex 2016; USEPA, 1986).

Soil gas samples submitted for report 10357548 were collected under a helium shroud to detect leaks in the collection system. The samples were non-detect for helium.

The data are considered acceptable for their intended use, with the appropriate data qualifiers assigned.

HOLDING TIMES, PRESERVATION, AND SAMPLE STORAGE

Holding Times

Extractions and analyses were performed within the recommended holding-time criteria.

Preservation and Sample Storage

The samples were preserved and stored appropriately.

BLANKS

Method Blanks

Laboratory method blank analyses were performed at the required frequencies. For purposes of data qualification, the method blanks were associated with all samples prepared in the analytical batch. All method blank results were below reporting limits.

Trip Blanks

Trip blanks were not required for this sampling event.

MATRIX SPIKE/MATRIX SPIKE DUPLICATE RESULTS

Matrix spike/matrix spike duplicate (MS/MSD) results are used to evaluate laboratory precision and accuracy. MS samples were extracted and analyzed at the required frequency.

In report A6H0076, several USEPA Method 6020A (batch 6080431) MS metals results were outside of acceptance criteria. The sample used to prepare the MS was from an unrelated project; thus, no results were qualified.

All remaining recoveries were within acceptance limits.

LABORATORY DUPLICATE RESULTS

Duplicate results are used to evaluate laboratory precision. Results less than five times the reporting limit were not evaluated for RPD exceedances. All duplicate samples were extracted and analyzed at the required frequency.

All RPDs were within acceptance limits.

LABORATORY CONTROL SAMPLE/LABORATORY CONTROL SAMPLE DUPLICATE RESULTS

A laboratory control sample/laboratory control sample duplicate (LCS/LCSD) is spiked with target analytes to provide information on laboratory precision and accuracy. The LCS sample was analyzed at the required frequency.

All LCS analytes were within acceptance limits for percent recovery.

REPORTING LIMITS

Apex used routine MRLs for non-detect results except for samples requiring dilutions due to matrix interference. Some total-mercury reporting limits were additionally raised due to matrix interference. Pace Analytical used MDLs for non-detect results. Soil gas results between the MDL and MRL were qualified "J" as estimated by the laboratory.

DATA PACKAGE

The data packages were reviewed for transcription errors, omissions, and anomalies.

In report A6H0076, a sample named "Bead Blank" was included in the sample list of the report. The reviewer confirmed with the laboratory that this was not a project sample. The laboratory indicated that the "bead blank" is part of the laboratory ISM quality-control process.

In report 10357548, the laboratory indicated that the USEPA Method TO-15 internal standard results for sample B6-SV-10.0 were below acceptance criteria. The results were confirmed by reanalysis; thus, no results were qualified.

No other issues were found.

ATTACHMENT D DEQ MEETING MINUTES

MEETING NOTES

| Meeting Topic and | OSU Cascades Demolition Landfill Engineering Due |
|----------------------|---|
| Number: | Diligence Status |
| Meeting Date & Time: | September 7, 2016, 10:00 – 11:30 a.m. |
| Project Number: | 1290.01.01 |
| Project Name: | Oregon State University – Cascades Campus Demolition Landfill Engineering Due Diligence |
| Meeting Location: | DEQ Eastern Region Office, 400 E Scenic Drive, Building 2, The Dalles, OR |
| Recorded By: | Ted Wall, Stacy Frost |
| Attendees: | Tammy Wisco, Retia Consult (via telephone) Joe Gingerich, DEQ Bob Schwarz, DEQ Stacy Frost, MFA Ted Wall, MFA |
| Distribution: | All attendees, file |

Meeting Agenda:

- 1. Background and primary issues per DEQ J. Gingerich
- 2. OSU planning process, status T. Wisco
- 3. Engineering due diligence status S. Frost
- 4. Prospective Purchaser Agreement and solid waste regulatory framework T. Wall
- 5. Next Steps/Action Items All

Background and Primary Issues per DEQ:

This was the first meeting on this subject and MFA asked to begin with an overview of J. Gingerich's observation and thoughts on primary issues associated with the landfill. Issues covered include:

- 1. Possible landfill gas (LFG) migration from Area 1 to adjacent commercial businesses to the east of the landfill warranted installation of a grid of LFG monitoring wells on the eastern property line, providing full-time coverage. No excess levels have been detected, but this condition warrants continued monitoring to ensure safety. LFG in Area 1 is a primary factor; safety at the landfill boundary is paramount.
- 2. Pyrolysis in Area 1 is also a primary factor, potentially impacting available options, material handling, final closure, etc. For example, excavation and material handling may change conditions, which will need to be controlled, e.g. cooling and replacement may alter LFG production rates.
- 3. Areas 2 and 3 are more "traditional" construction debris landfill cells, likely requiring routine material handling processes only.
- 4. Hoped to see excavation within the pyrolysis area as part of the pilot study that may have provided insight about working with the waste, e.g. will exposure to air cause a flare or cool down the material?

OSU Planning Process:

T. Wisco described her role as OSU's Project Manager (on contract) for the landfill due diligence, as well as land use approval processes for the future campus expansion.

The 10-acre parcel has been developed with students arriving now. The university purchased the adjacent 46-acre pumice mine last year, with long-range planning under development now. A primary question through this process is whether the university and community needs can be met by the currently owned parcels (56 acres) or whether the 70+ acres represented by the landfill are needed. This in turn leads to questions about the viability, cost, and risk associated with the landfill property.

The ongoing long-term planning process involves Page and SERA architects. They are supporting the understanding and development of programming needs, space planning, lay-out, etc. Understanding the potential options and limitations associated with development within the landfill footprint is informing the long-term planning, which is an iterative process.

Engineering Due Diligence

S. Frost summarized the findings to date and how they may impact decision-making and landfill closure.

- As previously discussed, Area 1 is the most challenging due to volume and depth of waste, waste type, etc. The waste has a large fraction of sawdust, which is less attractive for alternate uses (e.g. as a hog fuel substitute, mulch, high-grade compost). The group discussed 1) materials handling, phasing (generally), grade constraints, possible use at Knott Landfill as a daily and final cover material (approximately 200,000 - 300,000 cubic yards are needed at Knott Landfill), etc.
- 2. Removal and off-site disposal of all waste was assessed and rejected due to multiple factors including cost, consumption of Knott Landfill air space, damage to roads, high traffic, etc.
- 3. Possible options include material handling elsewhere on-site, composting on- or offsite, placement elsewhere on-site, etc.
- 4. Cover soil in Area 1 would be removed and used as backfill. Soil from other areas on-site could be mined for use as backfill material. Backfill volume needs could be reduced by deliberate planning and facility layout, e.g. build underground parking structures in Area 1.
- 5. Areas 2 and 3 are less problematic, but still require materials handling, phasing/timing, etc. Looking at these areas in conjunction with Area 1, on-site soil sources, backfill opportunities, and specific land uses (e.g. open space in areas where waste is placed) are all factors in play.

Prospective Purchaser Agreement, Solid Waste Regulatory Framework

T. Wall discussed the possible pursuit of a Prospective Purchaser Agreement (PPA) and how the landfill closure/post-closure requirements may be addressed:

- 1. The four criteria for PPA eligibility are: 1) the Buyer is not a liable party, 2) an environmental impairment exists, 3) the Buyer will perform actions that will enhance environmental conditions, and 4) there will be a public benefit. All four criteria are met.
- 2. Standard closure and post-closure requirements as stipulated in statute and regulation will be addressed, with an understanding that unique conditions exist and can be accommodated (e.g. landfill cap via parking lot).
- 3. Clear definition of obligations and obligation limits is necessary for the University to quantify (monetize) costs and minimize uncertainty/risk. The PPA is the only avenue that can provide this definition and certainty.

General Discussion

The items below were discussed throughout the course of the conversations summarized above. Where attributable, the specific attendees' comments are noted. The statements below represent general DEQ engagement in the discussion and are not formal determinations by the agency.

- 1. Timeframe, phasing:
 - a. The University will expand the facility in phases, and landfill redevelopment will necessarily also occur in phases.
 - b. The DEQ expects flexibility in implementation schedule can be accommodated, with interim milestones a necessary element of the PPA.
- 2. Materials handling and all aspects of redevelopment will involve multiple factors (e.g. dust control, noise control, and periods of operation). These will be spelled out in the PPA and subsequent planning documents, and thus will require DEQ approval.
- 3. Public education and ultimately acceptance will be an important factor in the success of this redevelopment, should the University proceed.
- 4. The DEQ will need to ensure compatibility with local and state land use requirements. (Note: conformance is a standard PPA obligation.)
- 5. T. Wisco summarized the current land use process:
 - a. The City's current UGB package includes code language for new mixed use zones, as well as changes to the City's Comprehensive Plan for several areas within the UGB. Once adopted by the City and acknowledged by DLCD, the OSU-C area will be re-designated on the Comprehensive Plan as Mixed Use Urban (MU) and is identified as an "Opportunity Area". It is anticipated that this package will be approved by the City in late September, for submittal to DLCD by October. Timeline is uncertain for the acknowledgement by DLCD.
 - b. The University will need to submit a zone change and master plan application for the expanded campus. This will likely occur after the DLCD acknowledgement of the UGB package.
- 6. T. Wisco reported that, based on County input, the University is working under the premise that purchasing only portions of the demo landfill site is not an option.
- T. Wisco reported that the Letter of Intent between the University and Deschutes County sets the purchase price as the fair market value minus the cost of remediation. If the cost of remediation is greater than the fair market value, the purchase price will be \$1.

- 8. T. Wisco reported that the University plans to make its go/no-go decision on the landfill in November 2016.
- 9. Moving waste within a permitted landfill site boundary is a normal process in landfill closure. The removal of waste from Area 1 and 2 and relocation to Area 3 is comparable.
- 10. DEQ confirmed that waste from Cell 1 would need to be farmed before reconsolidation in Area 3 first to protect against future pyrolysis creation.
- 11. DEQ indicated that considering the depth to ground water and climate, an argument could be made to exclude groundwater monitoring in the reconsolidated waste area.
- 12. With removal of all of the waste from Area 1 and 2, the permitted landfill boundary could be reduced to just Area 3, i.e. the PPA/permit boundaries will not include Areas 1 and 2 after this occurs.
- 13. Reuse of various portions of the waste (e.g. daily cover for Knott landfill, final cover for Knott landfill, compost, and soil amendment) could possibly meet DEQ's Beneficial Use Determination criteria.
- 14. The ultimate use of recycled materials will dictate the processes needed to ensure protection of human health and the environment:
 - a. Testing will differ if the material is used in ways that confine potential exposure (e.g. Knott Landfill cover soil) versus those that do not (e.g. compost production for wholesale/retail use).
 - b. Materials management on-site versus off-site.
- 15. There is an estimated 50,000 cubic yards of waste on adjacent Parks and Recreation land. This waste is outside of the permitted landfill, with the County and Parks and Recreation being the two responsible parties for proper management of this material. This waste is not currently within the property boundary that the University and Deschutes County are addressing, and would not be managed by the University if the landfill is purchased (unless done so through other negotiations/procedures).
- 16. The DEQ sees benefits to redevelopment in ways the University may pursue, and will work with and support the University, as needed. The DEQ sees this as a viable PPA candidate. Specifically, they see removal of the waste and extinguishing of the pyrolysis in Cell 1 as an environmental benefit.

Next Steps/Action Items:

| Item Number | Description | Person Responsible | Date Due |
|-------------|---|--------------------------------|--------------------------|
| 1 | Continue due diligence, progress report (telephone call) | T. Wisco, S. Frost, T. Wall | Approximately 9/21/16 |
| 2 | Internal DEQ assessment, progress report (telephone call) | J. Gingerich, B. Schwarz | Approximately 9/21/16 |

- 2. All waste in Cell 3 to remain in place.
- 3. Approximately 3% of all waste is not suitable for recycle or reuse and will be hauled off-site for disposal. Disposal cost by others.
- 4. Based on the results of the County's pilot study, the screened fines have an organic content up to 22%. Screened fines will be blended with soil sourced on-site at a ratio of 4.5:1 to produce a suitable backfill with an organic content not exceeding 4%.
- 5. This estimate is based on an averaged estimated quantities from the GBB report, and the County pilot study.
- 6. Assumes 15% contingency accounts for design of reclamation, monitoring during construction, and reflect unknown conditions (such as adverse weather conditions, material costs, or unfavorable market conditions).
- 7. The maintenance and monitoring cost associated with landfill Cell 3 is estimated to be approximately \$20,000 per year. This has not been included in this estimate.
- 8. Metals are not accounted for within the cost estimate, assuming that material reuse preparation and associated sales revenue are net-zero items.

| Cost Estimate S | Summary - Feasibility Level | | | | | | | | | | |
| Phase 3 Re Total Was | emediation Cost te Excavated | \$ | 25,6 88(| 6 04 0,8 | 1,923 63 су | | | | | | |

Assumptions:

- 1. Assumes remaining 82% of Cell 1 will be remediated for Phase 3. This estimate excludes the estimated 50,000 cy of waste located within the Bend Park and Recreation property.
- 2. This phased excavation of Area 1 assumes a similar constituent make up as identified in the original estimate, with the exclusion of tires.
- 3. Based on previous reports, this estimate assumes that all tires within Area 1 would have been encountered in the first phase of remediation.
- 4. All waste in Cell 3 to remain in place.
- 5. Pyrolysis material is not suitable for reuse and will be processed and relocated to Cell 3.
- 6. The active pyrolysis area is estimated to be approximately 75' wide, 1,390' long (along the entire pumice wall face on the east side of Area 1), 50' in depth based on the GBB report. Volume of active pyrolysis material is estimated to be 192,700 CY. This cost estimate assumes that 82% of this material will be encountered in the last phase of remediation.
- 7. Approximately 3% of all waste is not suitable for recycle or reuse (i.e. drums) and will be hauled off-site for disposal. Disposal cost by others.
- 8. Based on the results of the County's pilot study, the screened fines have an organic content up to 22%. Screened fines will be blended with soil sourced on-site at a ratio of 4.5:1 to produce a suitable backfill with an organic content not exceeding 4%.
- 9. This estimate is based on an averaged estimated quantities from the GBB report, and the County pilot study.
- 10. Assumes 15% contingency accounts for design of reclamation, monitoring during construction, and reflect unknown conditions (such as adverse weather conditions, material costs, or unfavorable market conditions).
- 11. The maintenance and monitoring cost associated with landfill Cell 3 is estimated to be approximately \$20,000 per year. This has not been included in this estimate.
- 12. Metals are not accounted for within the cost estimate, assuming that material reuse preparation and associated sales revenue are net-zero items.

| | Demolition Landfill Reclamation | | |

INTRODUCTION

GeoDesign, Inc. is pleased to submit this memorandum that presents our characterization of the demolition landfill. This memorandum briefly summarizes the background geologic information and current subsurface conditions within the landfill. We also identify geotechnical considerations for the potential redevelopment plan for the site.

Our findings are based on our review of existing information collected by others and our recent site reconnaissance for the approximately 75-acre Deschutes County demolition landfill site for the proposed extension to the Oregon State University Cascades Campus. Multiple previous subsurface and surface explorations have been completed on or adjacent to the Deschutes County demolition landfill site. Specifically we reviewed the following documents in preparing this memorandum:

- Gershaman, Brickner & Bratton, Inc. (GBB), *Demolition Landfill Subsurface Investigations Study, prepared for Deschutes County Department of Solid Waste, Bend Oregon*, dated October 31 2008. GBB Project Number C08016 (GBB, 2008)
- PBS Engineering + Environmental (PBS), *Phase II Characterization Report Groundwater Assessment Monitoring; Demolition Landfill; 19755 Simpson Avenue; Bend, Oregon*, dated June 2013. PBS Project No: 80570.000 (PBS, 2013)
- Carlson, Report of Supplemental Geologic Reconnaissance & Preliminary Slope Stability Analysis for Eastern Portion of OSU Cascades 46-Acre Site, 1707 & 1757 SW Simpson Avenue; Bend Oregon, dated May 21 2014. CGT Project Number G1303959.B (Carlson, 2014a)
- APEX, DRAFT Former Demolition Landfill Mitigation Evaluation; Deschutes County; Bend, Oregon, dated June 4 2014. Apex Project No. 1348-20 (APEX, 2014)
- Carslon Geotechnical (Carlson), *Report of Preliminary Geotechnical Investigation; OSU Cascades* 46-Acre Site; 1707 & 1757 SW Simpson Avenue; Bend Oregon, dated July 25 2014. CGT Project Number G1303959.A (Carlson, 2014b)

Memorandum

Page 2

We conducted a site reconnaissance and observed seven supplemental boring explorations completed by Maul Foster Alongi's subcontractor, Pacific Soil & Water, on July 28 and 29, 2016. The direct-push borings were advanced to depths ranging from 6.0 to 46.0 feet below ground surface (BGS). One of the borings (B7) was advanced to 46.0 feet BGS in landfill Area 3 to provide further geotechnical information on the depth and composition of cover materials for potential re-use as structural fill for the project. The additional subsurface information will be presented by Maul Foster Alongi in a separate document.

GEOLOGIC SETTING

Subsurface geology in the area is dominated by recent unconformable air-fall and pyroclastic units with locally variable degrees of consolidation and welding underlain by basaltic cinder and lava flows of the adjacent Overturf Butte Complex (Carlson, 2014b). In sequence, the following units are likely to be exposed in the relict quarry sidewalls and beneath landfill areas:

- Shelvin Park Tuff Dark gray andesitic to dacitic tuff with various volcanic lithic fragments, densely welded, and of generally blocky/columnar nature within the lower portion of the unit (Carlson, 2014a).
- *Tumalo Tuff* Light gray ryolitic air-fall tephra deposits (locally referred to as the Bend Pumice) overlain by a pyroclastic flow deposit of similar composition. Where exposed in outcrop, these units show varying degrees of consolidation and welding and generally exhibit moderate to poor consolidation (Carlson, 2014a).
- *Desert Spring Tuff* Dark gray to brownish orange ryodacitic ash flow tuff, moderate to well consolidated, with evidence of partial welding in the lower portion of the unit (Carlson, 2014a).
- Overturf Butte Complex Reddish brown to dark gray and black basaltic cinder, spatter, and flow
 deposits associated with the adjacent Overturf Butte Vent complex. Previous explorations have
 identified potential paleosols and weathering between flow and deposit margins within this unit
 (APEX, 2014).

Slope stability analyses were previously completed in order to provide slope gradient recommendations for the quarry site to the south (Carlson, 2014a). During our brief field reconnaissance we did not observe slope conditions in the south quarry different than identified by the prior report or any signs of inherent instability or slope failure under current conditions.

AREA 1

Access to Area 1 consists of a single road that is wide, well graded, and of gentle slope running from the north entrance to the center of the site, with a smaller track running east-west to a gate on the west side. The Area 1 fill has generally been built level to roughly 15 feet above the adjacent surrounding grades. While loose, the cap material provides a competent subgrade that can support light vehicular traffic. At the time of our reconnaissance surface vegetation in Area 1 consisted of light grass and sagebrush in immature soils (cap material), with the cap material sourced primarily from the Desert Springs and Tumalo Tuff units. The cap material can be generally classified as silty

GEODESIGN[¥]

Memorandum

Page 3

sand (SM) with gravel. Surface subsidence was observed in the majority of Area 1, with the exception of the roadways running through its central portion. Cracking, slumping, and some dark gray to black-stained, non-organic precipitation at fissures and cracks (within the zone undergoing pyrolysis) are generally present in subsiding areas. Areas undergoing pyrolysis were observed to have a distinct and acute non-organic odor at the surface. Deschutes County employees informed us that subsiding areas were periodically filled in with a stockpile of cap material located in the central area of the site, per their standard procedure for the surface of areas undergoing pyrolysis.

Previous explorations, and those observed by us, show cap thicknesses vary between approximately 0.5 foot and 10 feet, with thickness highly dependent on location (GBB, 2008). Portions of the cap material also appear intermingled with landfill material 0.5 foot to 10 feet below the base of the cap. Landfill material in Area 1 is likely more diverse than that found in Areas 2 and 3, and previous reports indicate approximately 43 percent of the landfill listed as uncharacterized, in addition to significant concentrations of tires and metal (APEX, 2014).

AREA 2

Surface vegetation and cap composition in Area 2 is very similar to Area 1, with some sagebrush significant enough to prevent passage of conventional vehicles. Two very steep access roads provide access to Area 2 on the north and west sides, with a small track blocked by boulders at the southwest boundary of the area. Area 2 fill has generally been built above the surrounding grades with the greatest slope heights up to approximately 45 feet and slope gradients up to approximately 1.5H:1V on the south edge of the area adjacent to the quarry to the south of the site. Subsidence, while not as severe as that observed in Area 1, is present in multiple locations in the center of Area 2, as well as evidence of some previously filled areas of subsidence.

Cap material observed in Area 2 is also very similar to that observed in Area 1. Cap thickness within Area 2 was generally observed by us and others to range between 0.5 foot and 5 feet with an average thickness of 2 to 3 feet (Carlson, 2014b; GBB, 2008). Landfill debris was observed in the sidewall of the landfill portion above original subgrade elevation. Stacked tires are present along the north side of Area 2, likely placed to stabilize the slope at the boundary of the landfill material. In the single boring exploration conducted in Area 2 while we were on site, landfill material was observed to consist primarily of sawdust, with minor amounts of construction debris (wood and fiberglass) observed in the 5 feet immediately below the base of the cap. Previous explorations of the landfill material in Area 2 generally show a mixture of wood waste, demolition waste, sawdust, and ash (GBB, 2008).

AREA 3

Surface vegetation in the landfill portion of Area 3 is very similar to Areas 1 and 2, with sparse grass, sagebrush, and a few small trees on the adjacent slopes. A main access road in fair condition rings the large depression in the middle of the quarry area and connects to the entrance off of SW Simpson Road in the north-central portion of the site. With the exception of the lowest area on the west side

GEODESIGNZ

Memorandum

Page 4

of the depression and above the access road at the northwest corner, the majority of the landfill area is accessible by conventional highway vehicles. A slope with gradients of roughly 3.5H:1V is present below the access road down to the gently sloping bottom in the middle of the Area 3 depression. The slope height increases up to approximately 40 feet at the west end of the depression. Slopes with variable gradients of up to approximately 1.5H:1V and slope heights up to approximately 40 feet are present immediately above the west end of the circular access road. Slopes with gradients up to approximately 2H:1V and slope heights of 15 feet are present immediately above the south side of the circular access road. We did not observe any signs of instability or failures of the existing slopes. Subsidence and some associated surface cracking were observed at the north side of the bottom of the depression during our reconnaissance.

Cap material in this area is extremely similar to Area 1. But it appears to be very loose at the surface and contains a higher proportion of pumice, likely due to a higher percentage of Tumalo Tuff used as cap material. Cap thickness in this area ranged from 3 to 40 feet (Carlson, 2014b; GBB, 2008); these thicknesses were generally confirmed with subsurface explorations conducted while we were on site. Several intervals of perched water were observed in the fill material at depth during the course of explorations. Significant portions of the tuffaceous fill observed are dark in color and odiferous and may have been moved from an original location in another area with close proximity to landfill material. Minor subsidence along the north side of the landfill area was observed, as well as concurrent cracking and void spaces in the adjacent subgrade. Outcrop of the Desert Springs tuff was sporadically encountered in the south slope of Area 3 up to 40 feet above the base of the slope. According to the previous studies, the majority of the waste material found in Area 3 consists of mixed demolition waste, wood waste, ash, and other unidentified materials (GBB, 2008).

DISCUSSION AND GEOTECHNICAL CONSIDERATIONS

We understand current development plans are to remove and process the landfill material from Areas 1 and 2 to reduce the amount of landfill material to the extent feasible. Beneficial uses will be sought for materials, including generation of material that can be used as structural fill to re-grade the excavations and other areas of the OSU Cascades Campus development. Removal of the landfill materials and replacement with structural fill will allow structures in Areas 1 and 2 to be supported on conventional shallow foundations. The cap material for Area 3 may also be removed and re-used for structural fill. Unusable landfill material from Areas 1 and 2 may be placed to fill in the depression of Area 3.

Past pumice mining within Area 1 created a near-vertical slope up to roughly 60 feet high at the eastern boundary of the excavation prior to being filled with landfill material. The steep cut stood for some time and would likely stand at the same configuration if exposed again from the removal of landfill materials. However, the exposed slope will likely have an unacceptable factor of safety since the three buildings are now located adjacent to the property boundary. We believe that the most cost-effective way to stabilize the slope will be to shore the slope using a soil nail wall as the waste is excavated. We recommend conducting explorations adjacent to the landfill in the native

GeoDesign[¥]

Memorandum

Page 5

predominantly tuff and pumice to evaluate and design the actual required slope reinforcement prior to exposing the near-vertical slope in proximity to the existing developments near the eastern property boundary.

While significant amounts of cap material exist on site, especially in Area 3, we observed significant transition zones in the recent explorations where cap material is mixed with landfill waste prior to the transition into landfill material. The majority of the cap material appears geotechnically suitable for placement and compaction as structural fill; however, due to the mixing with waste in the transition zones, we expect some material will have to be selectively excavated and processed to remove deleterious materials prior to placement and compaction as structural fill.

We understand the landfill materials may be processed to separate the soil from other landfill debris for re-use as structural fill. The processing may not remove enough organics from a geotechnical perspective for immediate re-use as structural fill. The decrease in geotechnical engineering properties of fill material is more significant with organic content exceeding approximately 4 percent. Therefore, we recommend a target maximum organic content of 4 percent for fill to be re-used as structural fill for the development. The fill can be mixed with clean material to decrease the organic content as necessary. Any organic material present in structural fill material should be uniformly mixed with the fill and less than ¼ inch in diameter. If trace organics are present in the fill, suitable construction observation and laboratory testing should be conducted to evaluate if organics in the fill are being limited to acceptable amounts. We further recommend structural fill be relatively free of organic material for the top 1 foot of fill below slabs and pavements and the top 2 feet below. foundations.

We understand waste material will remain in Area 3; additional landfill waste may be placed in the area prior to the planned non-settlement-sensitive developments over the capped landfill area. New landfill materials for the area should be compacted to the extent feasible. The thickness of the cap fill over the area should be based on the planned overlying developments; however, a preliminary cap thickness of 5 to 10 feet could be assumed for planning purposes. The cap may also incorporate geosynthetic reinforcement to limit differential settlement. Depending on the final depth, configuration, observed settlement rates, and planned non-settlement-sensitive developments, an extended surcharge on the order of 10 feet above the cap may also be required over the landfill area.
